Alternating chapters describe Moon mythologies and superstitions, the history of astronomical study, and the efforts involved in launching a lunar expedition, each of which is given a keyed label on the contents page. The photographs pop with color and action, and provide insight into such everyday activities as the astronauts eating breakfast contrasted with the massive machinery required to put them into space. The invaluable contribution of Muslim scientists is included in more than one of the "Moon Facts" chapters, which contrast the growth of scientific knowledge with lunar myths, stories, astrology, and science fiction. A one-page summary of Moon Facts provides quick reference, as does the Apollo Program time line. Scientists still aren't sure how the moon came to be, but they believe it is one of the keys to life evolving on Earth. Live Science is supported by its audience. The documentary Moon Mysteries, produced by the popular Naked Science series, seeks to fill in and explore these gaps in our understanding. The film opens by taking us back 4.5 billion to the time of the Moon's formation. The prevailing scientific consensus tells us that this event was precipitated by a violent collision with our planet. By unlocking additional details about the Moon's vast history, researchers hope they can also learn more about the evolution of our own planet, its earliest inhabitants and what fates may lie in wait for us all. In a series of thought-provoking interviews, several top figures in the world of science help us grapple with complex concepts. Mysteries | The theory accepted by most scientists about the origin of the Moon is that the Earth, barely formed, collided with another body, having almost the size of Mars. It is believed that our planet would not have been hit frontal but tangential, as it would just be called "œscalp". In 1970, Mihail Vasin and Alexander Shcherbakov, two Russian scientists from the Soviet Academy of Sciences, proposed the theory of the Moon as an alien ship. The two assumed that the Moon is a giant extraterrestrial ship that was covered with a rock to look like a natural satellite. It seems that in the history of mankind there was a time when there was no moon in the sky! This is made clear to us by the ancient writers Democritus and Anaxagoras. The story of the moon's history and processes is interesting in its own right, but it has also subtly shifted perspectives on our own origins. One of the most significant discoveries of the 1980s was the giant impact 65 million years ago in Mexico that led to the extinction of the dinosaurs, allowing the subsequent rise of mammals. This discovery (made possible by recognizing and interpreting the telltale chemical and physical signs of hypervelocity impact) came directly from the study of impact rocks and landforms stimulated by Apollo. A moon is an object that orbits a planet or another object that is not a star, although there are some exceptions - exoplanets are considered to be essentially wandering moons. These naturally occurring satellites are all over our solar system. In fact, it is estimated that there are around 200 moons just in our solar system alone. However, this does not make Earth's moon any less unique. Humanity's historic first steps on the moon occurred a little over 50 years ago. Yet, with all of the effort we have put into traveling to the moon, we still do not know that much about the lunar surface. Alternating chapters describe Moon mythologies and superstitions, the history of astronomical study, and the efforts involved in launching a lunar expedition, each of which is given a keyed label on the contents page. The photographs pop with color and action, and provide insight into such everyday activities as the astronauts eating breakfast contrasted with the massive machinery required to put them into space. The chapters on mythology use art reproductions from many cultures across the centuries to show the worldwide and timeless fascination with the Moon, including science-fiction movies. The moon lacks much in the way of an atmosphere and hasn't been volcanically active for billions of years, which means its surface has remained relatively unchanged across the eons. In this sense, says Prabal Saxena, a postdoctoral researcher at NASA's Goddard Flight Center, the craters are like the pages of a history book of the early solar system "if only we could figure out how to read them." Strangely enough, the moon also appears to have recorded early solar history. Earlier this year, Saxena and his colleagues used the composition of the lunar crust to determine that our sun likely rotated 50 percent slower than similar newborn stars during its first billion years of life.
